

The Weighted Bootstrap

INTRODUCTION 1) Introduction In 1979, Efron introduced the bootstrap method as a kind of universal tool to obtain approximation of the distribution of statistics. The now well known underlying idea is the following: consider a sample X of X_i n independent and identically distributed H.i.d.) random variables (r. v.'s) with unknown probability measure (p.m.) P . Assume we are interested in approximating the distribution of a statistical functional $T(P)$ the n -th empirical counterpart of the functional $T(P)$, where $P_n := \frac{1}{n} \sum_{i=1}^n \delta_{X_i}$ is the empirical p.m. Since in some sense P is close to P_n when n is large, $n \rightarrow \infty$ from P and builds the empirical p.m. if one samples $X_1, \dots, X_n$ n -1 $n \rightarrow \infty$ $P_n \rightarrow P$ $T(P_n)$ conditionally on P_n $i=1, \dots, n$ then the behaviour of P_n $n \rightarrow \infty$ $T(P_n)$ should imitate that of when n and $n \rightarrow \infty$ get large. n This idea has lead to considerable investigations to see when it is correct, and when it is not. When it is not, one looks if there is any way to adapt it.
